

ABSTRACT OF THE DISCLOSURE

A voice mail service system is disclosed, which can be matched with a private switching system, and which enables the private switching system to provide a voice mail service without a separate voice mail service system. In the voice mail service system, a system matching section matches and interfaces information with the private switching system, and a voice data storage section provides a voice mail function for each extension subscriber connected to the private switching system, and stores voice guide information of the extension subscriber in an address sector of a corresponding channel after compressing the voice guide information. A voice and signal processing section stores voice data of the extension subscriber in the voice data storage section after compressing the voice data, and restores the compressed voice data applied from the voice data storage section, so that the voice data can be transmitted to a call-connected opponent. A communication control section manages a state of each channel matching with the private switching system, processes troubles of the channel, and maintaining and repairing the channel. A control section matches with the private switching system so as to generally control operation for maintaining the voice mail function.
